

## 40Hz Ultrasonic Range Detection Sensor

A guide to using the DYP-ME007 with Arduino in order to calculate distances from objects. In this case I'm also altering the output of an LED with PWM according to how close an object is to the sensor. So the nearer you are the brighter the LED.

So if we start with the DYP-ME007, it's an IC that works by sending an ultrasound pulse at around 40Khz. It then waits and listens for the pulse to echo back, calculating the time taken in microseconds (1 microsecond =  $1.0 \times 10^{-6}$  seconds). You can trigger a pulse as fast as 20 times a second and it can determine objects up to 3 metres away and as near as 3cm. It needs a 5V power supply to run.

Adding the DYP-ME007 to the Arduino is very easy, only 4 pins to worry about. Power, Ground, Trigger and Echo. Since it needs 5V and Arduino provides 5V I'm obviously going to use this to power it. Below is a diagram of my DYP-ME007, showing the pins. There are 2 sets of 5 pins, 1 set you can use, the other is for programming the PIC chip so don't touch them!

### 1、 Specification:

Working Voltage : 5V(DC)

Working Current : max 15 ma

Working frequency : 40HZ

Output Signal : 0-5V (Output high when obstacle in range)

Sentry Angle : max 15 degree

Sentry Distance : 2cm - 500cm

High-accuracy : 0.3cm

Input trigger signal : 10us TTL impulse

Echo signal : output TTL PWL signal

Size : 45\*20\*15mm

Note : This module is not suitable to connect with electric power, if you need to connect this module with electronic power, then let the GND terminal of this module to be connected first, otherwise, it will affect the normal work of the module

## 2、Interface:

1: VCC; 2: Trig; 3: Echo; 4: Out; 5: GND

## Pin:

1: VCC ; 2: trig (T); 3: echo (R); 4: OUT (Don't Connect) ; 5: GND

## 3、 Usage:

Supply module with 5V, the output will be 5V while obstacle in range, or 0V if not.

The out pin of this module is used as a switching output when anti-theft module, and without the feet when ranging modules,

Note : the module should be inserted in the circuit before been power, which avoid producing high level of misoperation ; if not, then power again.

Module Working Principle:

- (1) Adopt IO trigger through supplying at least 10us sequence of high level signal,
- (2) The module automatically send eight 40khz square wave and automatically detect whether receive the returning pulse signal,
- (3) If there is signals returning, through outputting high level

and the time of high level continuing is the time of that from the ultrasonic transmitting to receiving.

Test distance = (high level time \* sound velocity (340M/S) / 2,

**The circuit:**

Very, very simple circuit, I've used the breadboard to share the GND connection and to add the LED which I could probably have done with out the breadboard. You'll see the most complex thing is the code later on.

**The sketch:**

All the work is done here, I've added code that averages the distance readings to remove some of the jitter in the results as the DYP-ME007 is calculating distances very rapidly and there can be a lot of fluctuation. Also I convert the time in microseconds to distance by dividing the time by 58. Why 58? Well because if you take the time in microseconds for a pulse to be sent and received e.g. for 1 meter it takes about 5764 microseconds – at least from my wall anyway. If I divide this time by the distance in cm in I will get 57.64 so I just round this up – you can calculate distance in any other unit with this method.

Here I've also decided that for every cm under 255 my LED will get 1 step brighter. I've been lazy here for the sake of the sensors 3 metre range I didn't see the point in making this any more complicated. Otherwise I would calculate the brightness on the percentile of proximity out of total range.

```
// variables to take x number of readings and then average them
// to remove the jitter/noise from the DYP-ME007 sonar readings
const int numOfReadings = 10; // number of readings to take/ items in the
array
int readings[numOfReadings]; // stores the distance readings in an array
int arrayIndex = 0; // arrayIndex of the current item in the
array
int total = 0; // stores the cumulative total
int averageDistance = 0; // stores the average value
// setup pins and variables for DYP-ME007 sonar device
int echoPin = 2; // DYP-ME007 echo pin (digital 2)
int initPin = 3; // DYP-ME007 trigger pin (digital 3)
unsigned long pulseTime = 0; // stores the pulse in Micro Seconds
unsigned long distance = 0; // variable for storing the distance (cm)
// setup pins/values for LED
int redLEDPin = 9; // Red LED, connected to digital PWM
pin 9
int redLEDValue = 0; // stores the value of brightness for the
LED (0 = fully off, 255 = fully on)
//setup
void setup() {
  pinMode(redLEDPin, OUTPUT); // sets pin 9 as output
  pinMode(initPin, OUTPUT); // set init pin 3 as output
  pinMode(echoPin, INPUT); // set echo pin 2 as input
  // create array loop to iterate over every item in the array
  for (int thisReading = 0; thisReading < numOfReadings; thisReading++) {
    readings[thisReading] = 0;
  }
```

```
// initialize the serial port, lets you view the
// distances being pinged if connected to computer
Serial.begin(9600);
}
// execute
void loop() {
digitalWrite(initPin, HIGH); // send 10 microsecond pulse
delayMicroseconds(10); // wait 10 microseconds before turning off
digitalWrite(initPin, LOW); // stop sending the pulse
pulseTime = pulseIn(echoPin, HIGH); // Look for a return pulse, it should be high
as the pulse goes low-high-low
distance = pulseTime/58; // Distance = pulse time / 58 to convert to
cm.
total= total - readings[arrayIndex]; // subtract the last distance
readings[arrayIndex] = distance; // add distance reading to array
total= total + readings[arrayIndex]; // add the reading to the total
arrayIndex = arrayIndex + 1; // go to the next item in the array
// At the end of the array (10 items) then start again
if (arrayIndex >= numOfReadings) {
arrayIndex = 0;
}
averageDistance = total / numOfReadings; // calculate the average distance
// if the distance is less than 255cm then change the brightness of the LED
if (averageDistance < 255) {
redLEDValue = 255 - averageDistance; // this means the smaller the distance the
brighterthe LED.
}
analogWrite(redLEDPin, redLEDValue); // Write current value to LED pins
Serial.println(averageDistance, DEC); // print out the average distance to the
debugger
delay(100); // wait 100 milli seconds before looping
again
}
```

**Example Code:**

```
////////////////////////////////////
//
// PIC16F877 + DYP-ME007 + LCD03 example
// Written October 2005 by Gerald Coe, using HITECH PIC16 compiler
//
// Note - assumes a 20MHz crystal, which is 5MHz timer clock
```

```
//      A 1:4 prescaler is used to give a 1.25MHz timer count (0.8uS per tick)
//
//      This code is Freeware - Use it for any purpose you like.
//
/////////////////////////////////////////////////////////////////
